# Helical Structures of Cyclopentenebased $\alpha, \alpha$-Disubstituted $\alpha$-Amino Acid Homopeptides 

Masakazu Tanaka*a, Haruka Yakabib, Haruki Nakatanib, Atsushi Uedaª, Mitsunobu Doic , and Makoto Oba ${ }^{\text {a }}$

#### Abstract

The cyclopentene-based $\alpha, \alpha$-disubstituted $\alpha$-amino acid $\mathrm{Ac}_{5} \mathrm{c}^{=}$and its homopeptides, up to nonapeptides, were synthesized. The side-chain cyclopentene was expected to become symmetric, the C ${ }^{\alpha}$-carbon to be puckered, and other $\mathrm{C}^{\beta}, \mathrm{C}^{\beta^{\prime}}, \mathrm{C}^{\gamma}, \mathrm{C}^{\gamma}$-carbons to be coplanar. As expected, side-chain cyclopentene conformations became symmetric and $\mathrm{C}^{\alpha}$-carbons were puckered. Conformational studies using FT-IR absorption, ${ }^{1} \mathrm{H}$ NMR spectra, and X-ray crystallographic analyses revealed that $\mathrm{Ac}_{5} \mathrm{C}=$ homopeptides did not form a planar conformation, but assumed a $3_{10}$-helical structure, similar to cyclopentane-based $\alpha, \alpha$-disubstituted $\alpha$-amino acid homopeptides.

Keywords: Conformation • Cyclopentene • $\alpha, \alpha$-Disubstituted $\alpha$-amino acid $\cdot$ Helix $\cdot$ Peptide

## Masakazu

Tanaka graduated with a BSc degree in Pharmaceutical Sciences from Kyushu University in 1986, and then received an MSc degree from the same university. He became a Research Fellow at the Osaka Branch of the National Institute of Health Sciences Japan in 1988. In 1990, he was appointed as a Research Associate at Kyushu University. After receiving his PhD degree under the supervision of Professor Kiyoshi Sakai, he performed postdoctoral work with Professor Dieter Seebach's group in 1994 at ETH in Switzerland. He became an Associate Professor at the Graduate School of Pharmaceutical Sciences, Kyushu University (Professor Hiroshi Suemune's group) in 1997. Since 2008, he has been a Professor at the Graduate School of Biomedical Sciences, Nagasaki University. He received the Yamanouchi Seiyaku Award in Synthetic Organic

Chemistry, Japan (1993), the Inoue Research Award for Young Scientists (1994), and the Pharmaceutical Society of Japan Award for Divisional Scientific Promotion (2006). His current research interests involve foldamers, asymmetric catalysts, and cell-penetrating peptides.

## 1. Introduction

$\alpha, \alpha$-Disubstituted $\alpha$-amino acids (dAAs) are non-coded amino acids that have an $\alpha$-alkyl substituent instead of an $\alpha$-hydrogen atom. ${ }^{[1-3]}$ dAA homopeptides have been reported to form stable secondary structures, such as $\alpha$-helices, $3_{10}$-helices, and extended planar structures. ${ }^{[4,5]}$ For example, $\alpha$-aminoisobutyric acid (Aib)containing homopeptides preferentially form $3_{10}$-helical structures, ${ }^{[6]}$ while diethylglycine (Deg)-containing homopeptides adopt extended planar conformations. ${ }^{[7,8]}$ Furthermore, cyclic 1-aminocycloalkanecarboxylic acid ( $\mathrm{Ac}_{\mathrm{n}} \mathrm{c} ; \mathrm{n}=$ ring size)-containing homopeptides are known to preferentially assume $3_{10}$-helical structures. ${ }^{[9]}$

For example, 1-aminocyclopentanecarboxylic acid $\left(\mathrm{Ac}_{5} \mathrm{c}\right)$ homopeptides were found to preferentially form $3_{10}$-helical structures. ${ }^{[10]}$ The side-chain cyclopentane ring formed an envelope conformation, and the puckered carbon was scrambled at the $\mathrm{C}^{\alpha}, \mathrm{C}^{\beta}$, and $\mathrm{C}^{\gamma}$ carbons (Fig. 1). On the other hand, the cyclopentene ring is flatter than the cyclopentane ring, and four carbons may be coplanar in the cyclopentene ring, while the other carbon is puckered. We designed an achiral 1-aminocyclo-pent-3-enecarboxylic acid $\left(\mathrm{Ac}_{5} \mathrm{c}^{-}\right),{ }^{[11]}$ in which the $\mathrm{C}^{\alpha}$ atom may be puckered and four other carbons $\left(C^{\beta}, C^{\beta}, C^{\gamma}, C^{\gamma}\right)$ are coplanar. We anticipated whether $\mathrm{Ac}_{5} \mathrm{c}^{=}$ homopeptides, when constructed, form a symmetric planar conformation because the cyclopentene ring may be symmetric and a rigid structure. In the case that $\mathrm{Ac}_{5} \mathrm{c}=$ homopeptides form helical structures, a comparison of helical structures between cyclopentane-amino acid $\mathrm{Ac}_{5} \mathrm{c}$ and cyclo-pentene-amino acid $\mathrm{Ac}_{5} \mathrm{c}^{=}$peptides may be of interest because $\mathrm{Ac}_{5} \mathrm{c}$-containing peptides may be used as cell-penetrating peptides ${ }^{[12]}$ and helical chiral catalysts. ${ }^{[13]}$

Fig. 1. Conformational flexibilities of the cyclopentane-based amino acid $\mathrm{Ac}_{5} \mathrm{C}$ and cyclopentene-based amino acid $\mathrm{Ac}_{5} \mathrm{C}=$. -

[^0]We herein synthesized the cyclopenteneamino acid $\mathrm{Ac}_{5} \mathrm{c}^{=}$, prepared its homopeptides, up to nonapeptides, and investigated their conformations in solution and in the crystalline state.

## 2. Synthesis of the Cyclopentenebased $\alpha, \alpha$-Disubstituted $\alpha$-Amino Acid $\mathrm{Ac}_{5} \mathrm{c}^{=}$and its Homopeptides

The cyclic amino $\operatorname{aridAc}_{5} \mathrm{c}^{=}$was synthesized as described previously ${ }^{[11,14]}$ (Scheme 1). Dimethyl malonate was dialkylated with cis-1,4-dichloro-2-butene by LiH to give the cyclic diester $\mathbf{1}$ in $71 \%$ yield. ${ }^{[14]}$ The monohydrolysis of diester $\mathbf{1}$ with aqueous NaOH , followed by the Curtius rearrangement with diphenyl phosphoryl azide (DPPA) and work-up with ${ }^{\dagger} \mathrm{BuOH}$ afforded the cyclopentene-amino acid Boc-( $\left.\mathrm{Ac}_{5} \mathrm{c}^{=}\right)$OMe (2) in 74\% yield. The hydrolysis of 2 with aqueous NaOH gave the $C$-terminal free amino acid Boc-( $\left.\mathrm{Ac}_{5} \mathrm{c}^{\mathrm{c}}\right)$-OH in quantitative yield, and deprotection of Bocprotecting group in 2 with 2 M methanolic HCl gave an $N$-terminal free amino acid $\mathrm{H}-\left(\mathrm{Ac}_{5} \mathrm{c}=\right)$-OMe in quantitative yield. Dipeptide (3) was prepared by coupling between $\mathrm{Boc}-\left(\mathrm{Ac}_{5} \mathrm{c}^{=}\right)$-OH and $\mathrm{H}-\left(\mathrm{Ac}_{5} \mathrm{c}^{=}\right)$OMe using 1-[bis(dimethylamino) methylene]- 1 H -benzotriazolium 3 -ox-
ide hexafluorophosphate (HBTU) and 1-hydroxybenzotriazole (HOBt) in $53 \%$ yield. Deprotection of Boc-protecting group in dipeptide 3, and the resulting dipeptide amine was coupled with Boc( $\mathrm{Ac}_{5} \mathrm{c}=$ )-OH using $O$-(7-azabenzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (HATU) and 1-hydroxy-7-azabenzotriazole (HOAt) to give a tripeptide $\mathrm{Boc}-\left(\mathrm{Ac}_{5} \mathrm{c}^{=}\right)_{3}-\mathrm{OMe}$ (4) in $75 \%$ yield. Hexapeptide $\mathrm{Boc}-\left(\mathrm{Ac}_{5} \mathrm{c}=\right)_{6}-\mathrm{OMe}$ (5) was prepared by the fragment coupling between tripeptide-carboxylic acid and tripeptide-amine in $75 \%$ yield. Similarly, nonapeptide $\mathrm{Boc}-\left(\mathrm{Ac}_{5} \mathrm{C}\right)_{9}$ - -OMe (6) was prepared by the coupling between hexa-peptide-amine and tripeptide carboxylic acid in $12 \%$ yield.

## 3. Conformational Analysis of Homopeptides in Solution

The FT-IR absorption spectra of $\mathrm{Ac}_{5} \mathrm{c}=$ homopeptides $\operatorname{Boc}-\left(\mathrm{Ac}_{5} \mathrm{c}^{=}\right)_{\mathrm{m}}$ - OMe (m $=$ $3,6,9$ ) in $\mathrm{CDCl}_{3}$ showed weak bands in the $3420 \sim 3430 \mathrm{~cm}^{-1}$ region, which were assigned as hydrogen bond-free, solvated $\mathrm{N}-\mathrm{H}$ groups, and strong bands in the $3330 \sim 3360 \mathrm{~cm}^{-1}$ region, which were assigned as hydrogen-bonded $\mathrm{N}-\mathrm{H}$ groups. The relative intensity of the low-frequency

Scheme 1. Synthesis of the five-membered ring amino acid $\mathrm{Ac}_{5} \mathrm{C}^{=}$and its homopeptides.
band to the high-frequency band increased as the main-chain length increased (Fig. 2). These FT-IR absorption spectra were very similar to those of the saturated $\mathrm{Ac}_{5} \mathrm{c}$ homopeptides. ${ }^{[10]} \quad \mathrm{Ac}_{5} \mathrm{c}^{=}$homopeptides do not have an $\alpha$-hydrogen atom, and, thus, it was not possible to apply nuclear Overhauser effect (NOE) correlations using $\alpha$-hydrogen. We measured correlations between $\mathrm{N}(n)-\mathrm{H}$ and $\mathrm{N}(n+1)$-H in NOESY NMR spectra. The complete series of sequential $d_{\mathrm{NN}}$ correlations between $\mathrm{N}(n)-\mathrm{H}$ and $\mathrm{N}(n+1)-\mathrm{H}(n=1 \sim 5)$ were observed in the NOESY NMR spectrum of hexapeptide 5 , and sequential $d_{\mathrm{NN}}$ correlations between $\mathrm{N}(n)-\mathrm{H}$ and $\mathrm{N}(n+1)-\mathrm{H}(n=1 \sim 8)$ in nonapeptide 6 were observed, except for the case of $n=4$ at which signals overlapped (Fig. 3). These results suggested the formation of a helical conformation. Furthermore, ${ }^{1} \mathrm{H}$ NMR measurements were performed following the addition of the strong hydrogen bond acceptor solvent DMSO- $d_{6}$ or the paramagnetic free radical 2,2,6,6-tetramethylpiperidin-1-yloxyl (TEMPO) to $\mathrm{CDCl}_{2}$ solution. The addition of DMSO- $d_{6}$ affected chemical shifts in two $\mathrm{N}-\mathrm{H}$ protons, and two $\mathrm{N}-\mathrm{H}$ peaks shifted to lower magnetic fields with an increase in DMSO- $d_{6}$. Furthermore, the addition of the TEMPO radical broadened the peak width of two $\mathrm{N}-\mathrm{H}$ protons (Fig. 4). These two N-H protons were solvated, and not intramolecularly hydrogen-bonded, suggesting the formation of helical structures in homopeptides 5 and 6. ${ }^{[10]}$

Fig. 2. FT-IR absorption spectra of Boc- $\left(\mathrm{Ac}_{5} \mathrm{C}=\right)_{\mathrm{m}}$ -OMe $4(m=3), 5(m=6)$, and $6(m=9)$ in $\mathrm{CDCl}_{3}$. A cell with $0.1-\mathrm{mm}$ path length was used. Peptide concentration: 5.0 mM .

## 4. Secondary Structural Analysis in the Crystalline State

The $\mathrm{Ac}_{5} \mathrm{c}=$ tripeptide 4 yielded a suitable crystal for X-ray crystallographic analysis by the slow evaporation of a mixture of $\mathrm{CHCl}_{3}$ and $\mathrm{MeOH} .{ }^{[15]}$ In the asymmetric unit, there was a $\beta$-turn structure. The structure was solved in the monoclinic centrosymmetric $P 2_{l} / n$ space group.

Fig. 3. NOESY NMR spectra of $\operatorname{Boc}-\left(\mathrm{Ac}_{5} \mathrm{C}\right)_{\mathrm{m}}$ OMe a) $5(\mathrm{~m}=6)$ and b) $6(\mathrm{~m}=9)$ in $\mathrm{CDCl}_{3}$.

Thus, the mirror image, right-handed and left-handed turn conformers, existed in the crystalline state. The $\phi$ and $\psi$ torsion angles were $\pm 60.6$ and $\pm 36.3$ in residue (1) and $\mp 55.5$ and $\mp 33.3$ in residue (2), respectively, whereas those of residue (3) had the opposite signs of $\pm 49.2$ and $\pm 43.8$, respectively. This kind of reversal of C-terminal torsion angles to those of the preceding residues was also observed in achiral $\mathrm{Ac}_{5} \mathrm{c}$ homopeptides. ${ }^{[10]}$ An intramolecular hydrogen bond of the $i \leftarrow i+3$ type was observed between the oxygen of urethane $\mathrm{C}(0)=\mathrm{O}(0)$ and peptide $\mathrm{N}(3)-\mathrm{H}$ (Fig. 5).

Recrystallization of the $\mathrm{Ac}_{5} \mathrm{c}=$ hexapeptide 5 from DMF afforded crystals suitable for an X-ray crystallographic analysis. ${ }^{[15]}$ The crystal structure was solved in the $P 2_{l} / n$ space group to give a $3_{10}$-helical

Fig. 5. A $\beta$-turn structure of $\mathrm{Boc}-\left(\mathrm{Ac}_{5} \mathrm{c}=\right)_{3}-\mathrm{OMe}$ (4) as elucidated by X-ray crystallographic analysis.

Fig. 4. Plots of N-H chemical shifts in the ${ }^{1} \mathrm{H}$ NMR spectra of 5 (a) and 6 (c) as a function of an increasing percentage of $\mathrm{DMSO}-d_{6}$ added to the $\mathrm{CDCl}_{3}$ solution, and plots of the bandwidth of the $\mathrm{N}-\mathrm{H}$ protons of $5(\mathrm{~b})$ and $\mathbf{6}(\mathrm{d})$ as a function of an increasing percentage of TEMPO added to the $\mathrm{CDCl}_{3}$ solution.
structure with two DMF molecules in the asymmetric unit (Fig. 6). The space group $P 2_{l} / n$ is centrosymmetric, and, thus, righthanded and left-handed helical structures (mirror image) both exist. The average $\phi$ and $\psi$ torsion angles of residues (1~5) were $\pm 59.0$ and $\pm 23.7$, accompanied by the reversal of the C-terminal torsion angles ( $\mp 58.4$ and $\mp 38.2$ ). The $i \leftarrow i+3$ type intramolecular hydrogen bonds, which corresponded to the $3_{10}$-helical conformation, were formed between the oxygen of carbonyl $\mathrm{C}(i)=\mathrm{O}(i)$ and peptide $\mathrm{N}(i+3)-\mathrm{H}(i$ $=0 \sim 3$ ). The formyl oxygen of solvents DMF (A and B) were hydrogen-bonded to peptides $\mathrm{N}(1)-\mathrm{H}$ and $\mathrm{N}(2)-\mathrm{H}$, respectively. Table 4 shows the distance between the $\mathrm{C}^{\alpha}(i)$ atom and plane defined by $\mathrm{C}^{\beta}(i), \mathrm{C}^{\gamma}(i)$, $\mathrm{C}^{\gamma}(i)$, and $\mathrm{C}^{\beta^{3}}(i)$ atoms. These distances were shorter than those of the cyclopen-tane-based amino acid (>0.55 $\AA$ ), ${ }^{[10]}$ with

the side-chain cyclopentene rings on $\mathrm{Ac}_{5} \mathrm{c}^{=}$ residues (3), (4), (5), and (6) in particular becoming flatter. The cyclopentene rings were symmetric, and the $\mathrm{C}^{\alpha}$-carbons were puckered. The superimposed structures of Boc- $\left(\mathrm{Ac}_{5} \mathrm{c}=\right)_{6}-\mathrm{OMe}(5)$ and $\mathrm{Cbz}-\left(\mathrm{Ac}_{5} \mathrm{c}\right)_{6}-$ $\mathrm{O}^{\prime} \mathrm{Bu}$ from CCDC-1264125 (X-ray crystallographic analysis by C. Toniolo and coworkers ${ }^{[10]}$ ) is shown in Fig. 7. The peptide backbone structure of $\mathrm{Ac}_{5} \mathrm{c}^{\mathrm{c}}$ hexapeptide 5 matched that of the reported $\mathrm{Ac}_{5} \mathrm{c}$ hexapeptide except for C-terminal residue, whereas the conformation of the side-chain cyclopentene in $\mathrm{Ac}_{5} \mathrm{c}^{=}$differed from that of the cyclopentane in $\mathrm{Ac}_{5} \mathrm{c}$. (Tables 1-4)

## 5. Conclusion

Homopeptides composed of cyclopen-tene-based $\mathrm{dAA} ; \mathrm{Ac}_{5} \mathrm{c}^{=}$, up to nonapep-

Fig. 6. A $3_{10}$-helical secondary structure of $\mathrm{Boc}-\left(\mathrm{Ac}_{5} \mathrm{C}^{-}\right)_{6}-\mathrm{OMe}(5)$ as elucidated by an X-ray crystallographic analysis. a) View perpendicular to the helical axis and b) view along the helical axis.

Fig. 7. Superimposed structures of Boc$\left(\mathrm{Ac}_{5} \mathrm{C}^{-}\right)_{6}-\mathrm{OMe}\left(5 \text {; red) and Cbz-( } \mathrm{Ac}_{5} \mathrm{c}\right)_{6}-\mathrm{O}^{t} \mathrm{Bu}$ (CCDC-1264125; blue) reported by Toniolo and coworkers. ${ }^{[10]}$
tides, were synthesized. A conformational analysis using FT-IR absorption, and ${ }^{1} \mathrm{H}$ NMR spectra in $\mathrm{CDCl}_{3}$ solution revealed that $\mathrm{Ac}_{5} \mathrm{c}^{=}$homopeptides preferentially formed helical structures. An X-ray crystallographic analysis unequivocally showed that the $\mathrm{Ac}_{5} \mathrm{c}=$ hexapeptide formed a $3_{10}$-helical structure, but not a planar conformation, and the side-chain cyclopentene ring in $\mathrm{Ac}_{5} \mathrm{c}^{=}$homopeptides became flatter and $\mathrm{C}^{\alpha}$-carbons were puckered in the five-membered rings. The olefin in the cyclopentene-based amino acid $\mathrm{Ac}_{5} \mathrm{c}=$ and its peptides may be easily converted into several functional groups. ${ }^{[16]}$
